 - PCA: principal component analysis
 - LDA: linear discriminant analysis
- association rules

- Supervised learning

- classification
- regression

Machine learning: algorithms

Supervised learning:

- Classification: classification trees...
- Regression: linear regression, logistic regression, stepwise regression, regression trees...

Unsupervised learning:

- Clustering: k-means, k-medians, hierarchical clustering...
- Dimensionality reduction: principal component analysis, discriminant analysis...
- Association rule: a priori algorithm...

Machine Learning: use cases

Supervised learning:

- Classification: customer retention, fraud detection, image classification...
- Regression: market forecasting, population growth prediction...

Unsupervised learning:

- clustering: customer segmentation, recommender systems...
- dimensionality reduction: structure discovery, big data visualization...
- association rule: targetted marketing...

- Machine Learning overview
- Unsupervised learning
 - clustering
 - KMeans
 - hierarchical clustering
 - dimensionality reduction
 - feature selection
 - feature extraction
 - PCA: principal component analysis
 - LDA: linear discriminant analysis
 - association rules
- Supervised learning
 - classification
 - regression

Association rules: overview

Goal:

Find association relationships in large data sets.

How does it work?

When we look for association rules, some parameters have to be defined:

- **support** of an itemset: percentage of the data set which contains this itemset
- **confidence** of a rule $A \Rightarrow B$: $P(A \text{ and } B)/P(A)$. It means, the rule is true for at least that confidence value.
- **lift of a rule** ($A \Rightarrow B$): $\text{support}(A \cup B)/(\text{support}(A) * \text{support}(B))$. Lift > 1 means both occurrences are dependent on one other

Example: rules with support 0.40 and confidence 0.80

$\{\text{peanuts, coke}\} \Rightarrow \{\text{chips}\}$ means that:

- at least, a 40% of the cases included peanuts and coke
- in the cases where peanuts and coke were sold, chips were sold as well at least in a 80% of these transactions.

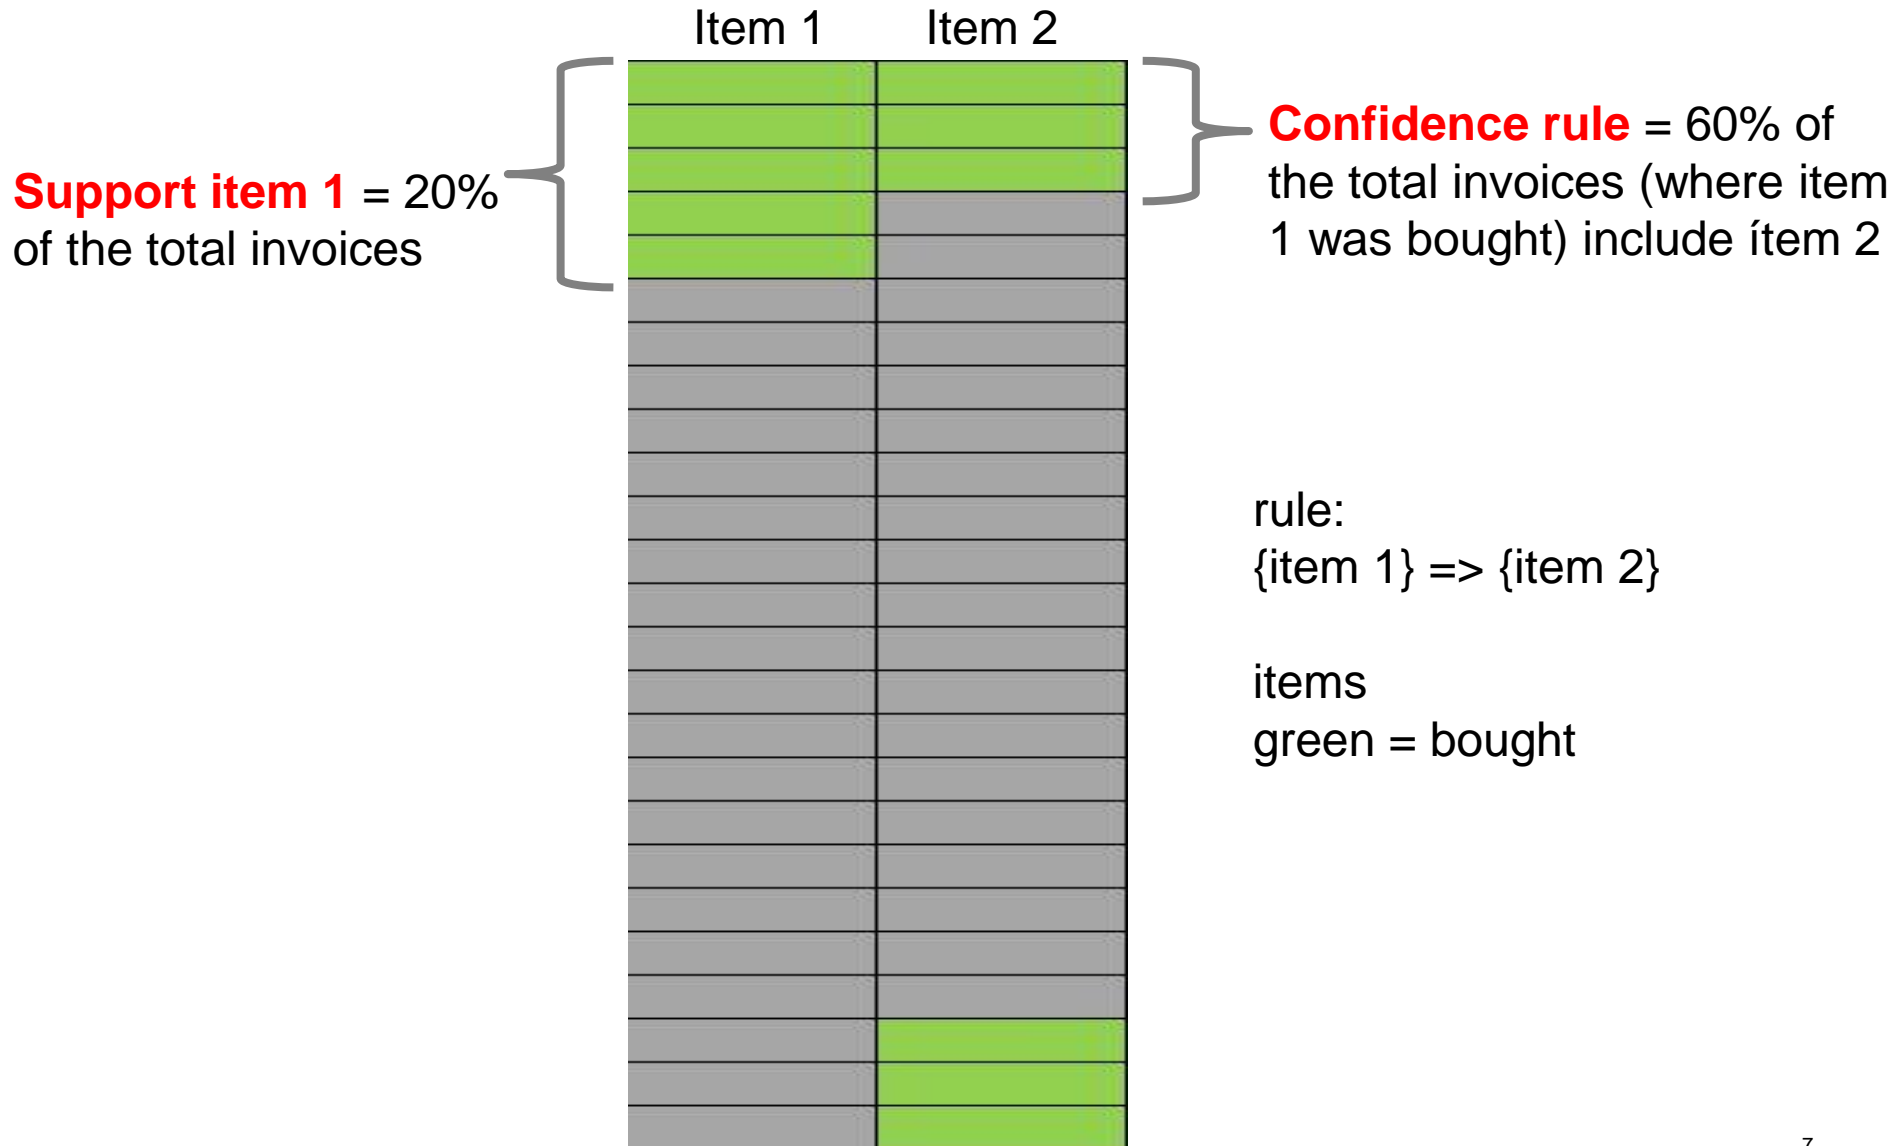

Usages:

Market analysis

Click stream tracking

Online recommendation engines

Selecting the support and confidence parameters

Association rules

```
from mlxtend.frequent_patterns import apriori, association_rules
```

```
frequent_itemsets = apriori(...)
```

Arguments in apriori command:

- df: dataframe in "Full binary vectors" format # columns: products. index: transactions IDs
- min_support: number
- use_colnames: True or False (default) # False: column indices. True: column names

```
rules = association_rules(frequent_itemsets, ...)
```

Arguments in association_rules command:

- df: frequent_itemsets
- metric: "lift" or "confidence" (default)
- min_threshold: number (default: 0.8)

Association rules: exercise

Programming challenge ARUL.1

File: association_rules_20000_XXX.csv

1. Give the correct structure to the data file in Python

Note: check the command `set_index`

2. Find a set of some rules

3. Try to quantify for some rule the number of non-sold units that we could try to sell doing recommendations

Association rules: exercise

Programming challenge ARUL.2

File: "Online Retail_Association rules_v2.csv"

1. Show the 3 items which have produced the highest income

Association rules: exercise

Programming challenge ARUL.2

File: "Online Retail_Association rules_v2.csv"

1. Show the 3 items which have produced the highest income
2. Give a calendar heatmap for the number of sold items per day in United Kingdom during December 2010 and January 2011

Association rules: exercise

Programming challenge ARUL.2

File: "Online Retail_Association rules_v2.csv"

1. Show the 3 items which have produced the highest income
2. Give a calendar heatmap for the number of sold items per day in United Kingdom during December 2010 and January 2011
3. Create the required structure to apply a association rules analysis for the invoices in France.

After this, calculate all the rules with lift > 1 for products sold in a 7% of the transactions at least.

4. For all the previous rules, extract the rules with lift > 6 and confidence is, at least, 80%.

Association rules: exercise

Programming challenge ARUL.2
